

# Base Conversion (Easy)

We want to make some base-conversion experiments. Here you can try basic methods.

## Input

The first line of input contains three integers  $T$ , the number of test cases,  $B1$ , the first base,  $B2$ , the second base.

Follow  $2 \times T$  lines.

For each test case, on the first line you are given one integer  $k$ .

On the second line you are given  $k$  integers : the digits of  $N$  in base  $B1$ .

$$N = a_0 \times B1^0 + \dots + a_i \times B1^i + \dots + a_{k-1} \times B1^{k-1}$$

## Output

For each test case, you have to print the number  $N$  in base  $B2$ . See sample for details.

## Example

**Input:**

```
1 10 100
5
5 4 3 2 1
```

**Output:**

```
3      <--- Don't forget the length of N in base B2 ;- )
45 23 1
```

## Explanations

For the lonely case,  $N = 5 \times 10^0 + 4 \times 10^1 + 3 \times 10^2 + 2 \times 10^3 + 1 \times 10^4 = 12345$ .

We have:  $N = 45 \times 100^0 + 23 \times 100^1 + 1 \times 100^2$ . You have to print 3, the number of digits, then the digits: 45, 23 and 1.

## Constraints

```
0 < T <= 200
1 < B1, B2 <= 10^9
1 < k <= 1000
0 <= a_i < B1 , a_{k-1} > 0
```

If you find the constraints too easy, then you should try [BASECONV](#).

The basic solution should give AC in 1.56s with Python3.

**Have fun ;-)**
