## Rainbow

This time Blue Mary continues doing meaningless calculations! (see problem SPY) She is interested in calculating the K-th power of a very large $\mathbf{N} \times \mathbf{N}$ matrix $A$, where
$A_{i, j}=i^{*} \mathbf{D}+\boldsymbol{Q}$
$i$ and $j$ are 0 -based index of the row and column of element $A_{i, j}$, respectively.
Now she needs your help (again).
To keep the output small, you are only asked to output some of its elements.

## Input

Multiple test cases.
The first line of each test case contains 5 space-separated integers $\mathbf{N}, \mathbf{K}, \mathbf{D}, \mathbf{Q}, \mathbf{M}$ in this order. $\mathbf{M}$ lines follow, each contains two space-separated integers $\mathbf{R}_{\mathbf{i}}$ and $\mathbf{C}_{\mathbf{i}}$.

Input terminates by EOF.
All input numbers are non-negative integers and no more than $10^{9}$.( $\mathbf{D}, \mathbf{R}_{\mathbf{i}}$ and $\mathbf{C}_{\mathbf{i}}$ may be 0 , others must be positive integers.) $\mathbf{N}$ and $\mathbf{M}$ will be no more than $10^{5} . \mathbf{R}_{\mathbf{i}}$ and $\mathbf{C}_{\mathbf{i}}$ will be less than $\mathbf{N}$.

Input is almost uniformly-random generated, and the number of "large" test cases is relatively small.

## Output

For each test case output exactly $\mathbf{M}$ lines. Each line contains only one integer: The number at the $\mathbf{R}_{\mathbf{i}}$-th row and $\mathbf{C}_{\mathbf{i}}$-th column (0-based) of the matrix $\mathbf{A}^{\mathbf{K}}$. As the result may be quite large, output it modulo $10^{9}+2015$.

## Example

## Input:

1030110
00
11
22
33
44
55
66
77
88
99
22124

10
11

Output:
100
100
100
100
100
100
100
100
100
100
5
8
8
13
